

Morbidity and Mortality

Weekly
Report

U. S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE

PUBLIC HEALTH SERVICE

Prepared by the COMMUNICABLE DISEASE CENTER

For release April 19, 1963

ATLANTA 22, GEORGIA

Vol. 12, No. 15

PROVISIONAL INFORMATION ON SELECTED NOTIFIABLE DISEASES IN THE UNITED STATES AND ON DEATHS IN SELECTED CITIES FOR WEEK ENDED APRIL 13, 1963

INFLUENZA - One or more outbreaks of influenza-like disease have now been reported from 42 States and the District of Columbia. The State of Wyoming was the only one to report outbreaks for the first time this week. Influenza A₂ virus has been isolated or confirmed by serologic titer rise as the causative agent of one or more outbreaks in 33 States and the District of Columbia. The State of Utah reported confirmed outbreaks for the first time this week. Outbreaks have now subsided in most affected areas in the Eastern and Middle Western United States. Two additional localized outbreaks were reported from northern California during the week ending April 13. The number of pneumonia-influenza deaths reported for

108 cities this week continued to fall sharply for the fourth consecutive week, and has now reached a level below the epidemic threshold for the first time since January 5.

Californic - Two additional outbreaks of influenza-like illness have been reported from communities in northern California during the week ending April 13. Both reports have come from areas lying close to sites of recent localized outbreaks in Napa and San Joaquin Counties (MMWR Vol. 12, Nos. 12, 13).

Amador County reported over 200 cases, all occurring in a single boys' reformatory with a total population of about 850. A steady level of incidence had been noted

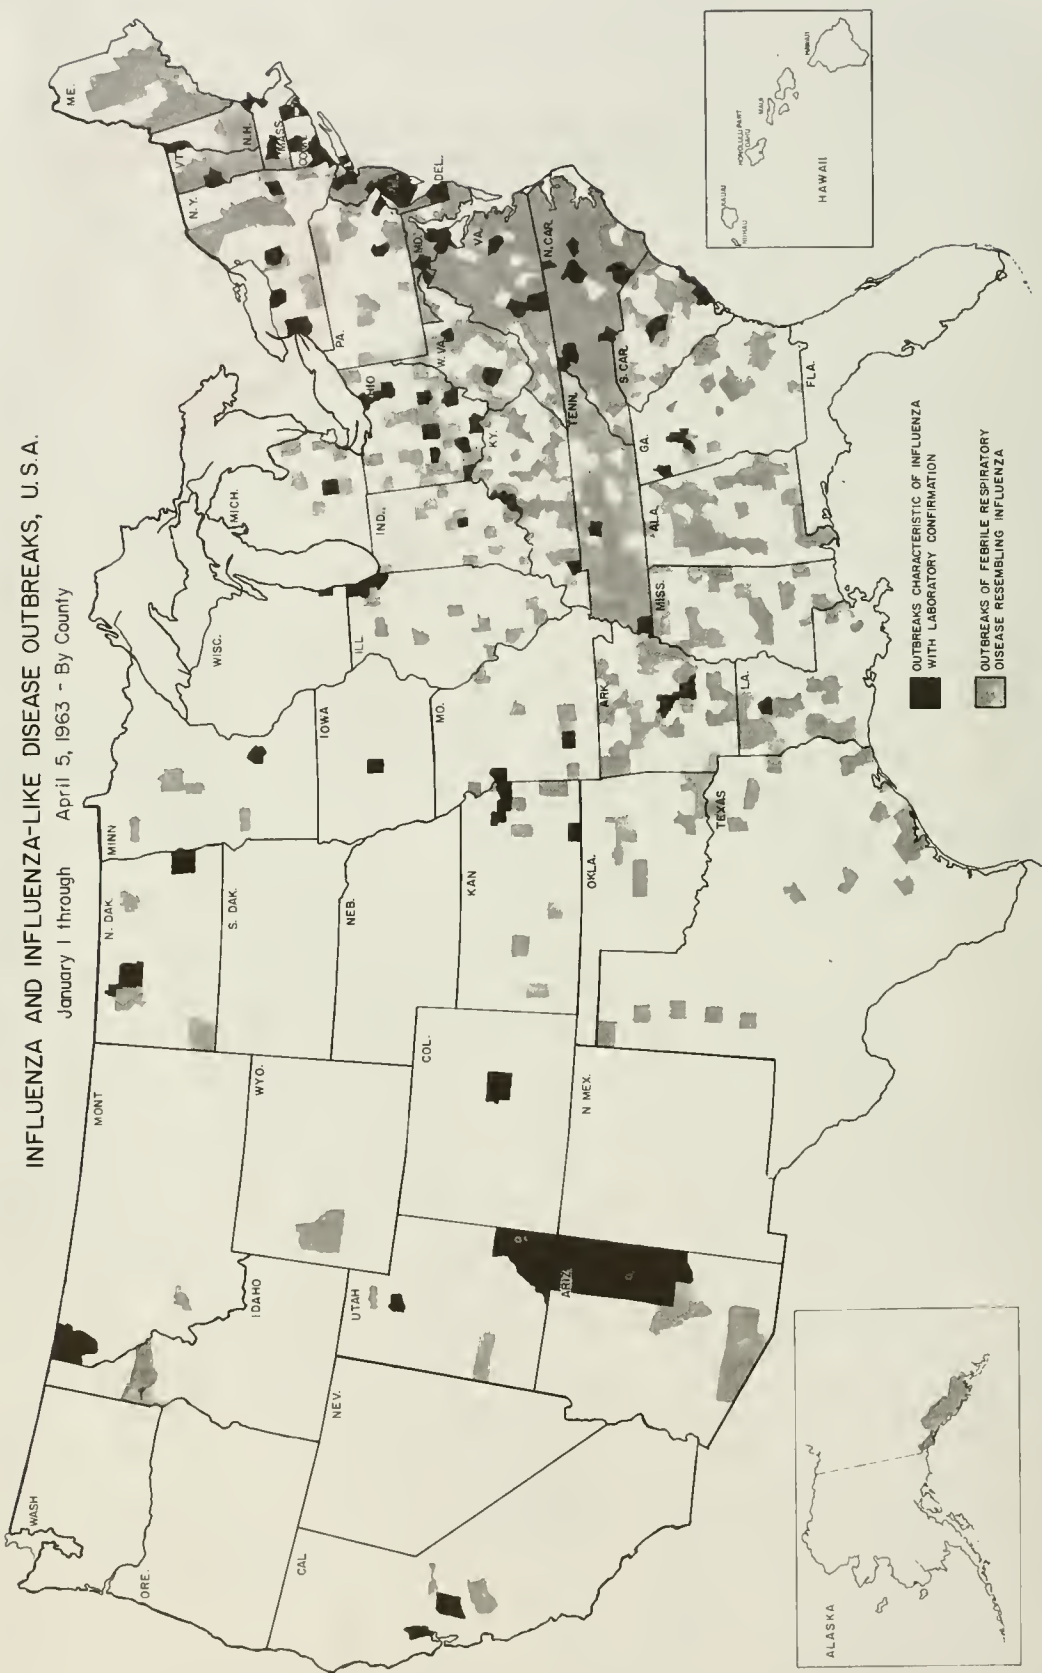

Table 1. CASES OF SPECIFIED NOTIFIABLE DISEASES: UNITED STATES

(Cumulative totals include revised and delayed reports through previous week)

Disease	15th Week			Cumulative

Plague:	-	Typhus, murine:	2

since the latter part of March followed by clear evidence of declining epidemic activity during the past week. The illness appeared typical of influenza clinically, although laboratory confirmation has not been obtained as yet.

A small community outbreak has been described in Merced County where an estimated 40-50 patients have been hospitalized with an influenza-like syndrome. Many additional cases have been noted in the surrounding community, the peak incidence having occurred in early April. This is the first reported outbreak in the State which has involved individuals outside of an institutional setting.

The State Viral and Rickettsial Disease Laboratory has thus far obtained serologic confirmation of influenza A₂ infection in a total of 47 cases from 18 counties, representing all geographic regions within the State. School absenteeism remains normal, but industrial absenteeism has shown some increase. It is the impression of State health authorities that there has been some influenza throughout the State, occurring mainly among adults, and in low enough concentration to escape routine surveillance measures.

(Reported by Dr. Philip K. Condit, Chief, Bureau of Communicable Diseases, California Department of Public Health).

Ohio – Influenza A₂ virus has been confirmed as the etiologic agent in outbreaks of acute febrile respiratory disease observed in the Columbus area earlier this year. It has been estimated that approximately 100,000 cases occurred during the epidemic, which reached its peak in late February. School and industrial absentee rates of 10-15% were observed at the height of the epidemic period. Outbreaks of influenza-like illness have now been reported from 36 of the State's 88 counties. Influenza A₂ virus has been confirmed as the etiologic agent in two or more cases in 10 of these 36 counties.

(Reported by Dr. Winslow Bashe, Division of Communicable Diseases, Ohio Department of Health).

Utah – Influenza A₂ virus infection has been confirmed serologically in two cases seen during recent outbreaks in San Juan County (MMWR Vol. 12, No. 14). Additional small community outbreaks have been reported from Weber and Salt Lake Counties, in the northern part of the State. Laboratory confirmation of influenza A₂ infection has been obtained in three cases from the Salt Lake outbreak.

(Reported by Dr. A. A. Jenkins, Director, Communicable and Chronic Disease Section, Utah State Department of Health).

Wyoming – A small outbreak of influenza-like illness has been reported from Sublette County in the western part of the State. The epidemic appeared to have reached its peak during the first week of April. Laboratory confirmation is not available as yet.

(Reported by Dr. Robert Alberts, Acting Director of Medical Programs, Wyoming Department of Public Health).

EPIDEMIOLOGICAL REPORTS

Erythema Infectiosum – Circleville, Ohio

In January 1963, following the Christmas holidays, an outbreak of mild exanthematous illness developed among children of the elementary school of Circleville, Ohio. Histories and physical examinations of 38 affected children elicited symptoms and signs suggestive of erythema infectiosum. A questionnaire sent home to parents of all students attending the school provided information for 286 households, with a total population of 1,259 individuals. One hundred and fifty eight cases of the illness were identified by this means.

Known onset dates for 149 of the cases (Figure 1) indicate the outbreak reached its peak during the week ending January 26; 85 percent of the cases occurred within a six-week period during January and early February. Clinically the disease was mild. Rash appeared in all cases, usually beginning on the face as a confluent red "butterfly" or as flat or slightly raised macules in the cheeks. The rest of the face typically remained clear,

although flexor and extensor surfaces of the arms, as well as abdomen and back, were frequently involved two to three days after appearance of the facial eruption. Frequently recurrent, the rash persisted in many cases for several weeks, unaccompanied by desquamation or hyperpigmentation. Distribution of symptoms among the 158 patients is given below:

TABLE 1

DISTRIBUTION OF SYMPTOMS OF ERYTHEMA INFECTIONOSUM
IN 158 PATIENTS

RASH	100%	SORE THROAT	23%
PRURITIS	53%	ABDOMINAL PAIN	23%
FEVER	41%	RUNNY NOSE	22%
HEADACHE	32%	SORE EYES	18%

The illness primarily involved individuals of both sexes in the elementary school age group (5-12 yrs.). Age distribution and age specific attack rates among those surveyed are given below:

TABLE 2

AGE SPECIFIC ATTACK RATES OF ERYTHEMA INFECTIONOSUM

AGE (YEARS)	POPULATION SURVEYED	NUMBER CASES	ATTACK RATE PER 100
0 - 4	116	21	18.1
5 - 12	444	119	26.8
13 AND OVER	699	18	2.6
TOTAL	1,259	158	12.5

Thirty-three percent of the pre-school children developing illness were siblings of school-age children previously affected. Fifteen percent of the pre-school cases occurred in families with no other affected members. A statistical evaluation of intervals between first and second cases in 35 households and 14 classrooms suggested an incubation period of 5-10 days.

Previous history of rubella, rubeola, and varicella were similar for both those ill and those not ill, but those individuals with a previous history of allergy seemed more likely to develop clinical evidence of the illness. Of the individuals surveyed who had no previous indication of allergic manifestations, 10.8% developed the illness, whereas 27.2 percent of those with previous history of allergic problems acquired the disease. This apparent increased susceptibility of allergic individuals was observed in both the under 13 and over 13 age groups.

A popular, putty-like compound known as "flubber" has been used quite extensively by children in the area in recent weeks. This material is composed of mineral oil and butadiene. Examination of the sales of flubber in the area (Figure 2) indicated that the outbreak occurred well

in advance of peak "flubber" distribution and failed to link this material in any way to the spread of the illness.

The epidemic curve and the spread within classrooms and homes seemed best explained by person-to-person contact transmission. Intensive bacteriologic and virologic laboratory investigations did not reveal any etiologic agent. (Reported by Winslow J. Bashe, M. D., M.P.H. Acting Chief, Division of Communicable Diseases, Ohio Department of Health; Mrs. Pauline Kirkpatrick, R.N., Pickaway County Health Department; and the Communicable Disease Center.)

Botulism - Canned Tuna - Supplemental Report

Since the death of two Michigan women due to Type E botulism acquired from commercially canned tuna (MMWR, Vol. 12, No. 12), intensive investigations have been conducted by the Food and Drug Administration, State, and local health departments. Tuna packed by the Washington Packing Company under several labels but identifiable by the code letters WY3 or WY2 (first three figures in the code) have been withdrawn from trade and laboratory study, particularly of defective cans, is in process.

The tuna involved was packed by the Washington Packing Company, San Francisco, at a new plant which began regular commercial operation in early January and terminated activities in early April. A few cases only of tuna were packed in December. Most of the production was shipped to the A & P Company as "A & P Chunk Tuna". This was promptly withdrawn by the company when the facts of the case were first known. Additional tuna packed under the tradenames "Tastewell" and "Ocean Beauty" was distributed only within California. That packed by the Washington Packing Company has been taken into custody by the California State Health Department. A quantity labeled Dagim brand packed for Dagim Tahorim

(Continued on page 126)

EXCESS MORTALITY IN 108 U.S. CITIES

During the week ending April 13 excess pneumonia-influenza deaths for the 108 cities fell below the epidemic threshold for the first time since the week ending January 5th. The excess was 14 deaths in comparison to 109 during the week ending April 6th. In all Divisions except the East and West South Central and Pacific, pneumonia-influenza mortality was near expected levels for this time of the year. In the East and West South Central States further declines brought excess mortality to slightly above the epidemic threshold. In the Pacific States a small increase in pneumonia-influenza deaths caused the weekly total to slightly exceed the epidemic threshold.

Excess mortality during the 1963 epidemic is compared with that of the 1960 epidemic in the accompanying chart. The upper panels show weekly excess mortality for comparable weeks of the two epidemics. The lower panels show cumulative excess mortality for each epidemic.

In 1963 excess pneumonia-influenza deaths increased later in the year and rose to a higher peak level than in 1960. However, the cumulative excess ascribed to pneumonia-influenza during the entire epidemic period was less in 1963 than in 1960.

Excess deaths from all causes at ages 65 and over and also at all ages, reached higher weekly levels in 1963 than in 1960 and the cumulative excess was also greater.

Infant Deaths - As shown in the accompanying table and bar chart, infant deaths were slightly below expected levels during the four week period ending April 13th.

INFANT DEATHS IN 108 CITIES

	WEEK ENDING				4 Week Total	Weekly Average
	3/23	3/30	4/6	4/13		
Observed	757	708	778	658	2,901	725
Expected	748	745	742	739	2,974	744
Excess	9	-37	36	-81	-73	-19

(See table, page 131)

Company, Brooklyn, and labeled "Tuna Kosher for Pass-over" has been embargoed by the New York City Health Department. Shipments of this brand to Pittsburgh, Cleveland, Baltimore, Detroit, Augusta, Georgia and a few other cities are presently being picked up.

Extensive laboratory testing of normal and suspect cans is being conducted by the FDA, by the California State Health Department and the Hooper Foundation, University of California. Preliminary results indicate type E, *C. botulinum* organisms to be present in a number of cans evidencing leakage or spoilage which were packed by this company at different times between early January and March.

To be emphasized is that only cans bearing the code WY2 or WY3 as the first letters in the code are presently suspect. This code identifies the packer and the year of packing. It should be noted that each tradename may include tuna from several packers; thus the tradename itself is not adequate identification.

(Reported by the Food and Drug Administration; the California State Health Department and Dr. K. F. Meyer, Hooper Foundation, University of California.)

INTERNATIONAL NOTES

Food Poisoning in British Columbia – An Unusual Etiology

In October 1962, three elderly couples developed vomiting and diarrhea shortly after eating a turkey supper. Samples of the turkey meat, dressing, cranberry sauce, and vomitus from the patients failed to reveal bacteriologic evidence of any of the usual food poisoning organisms. One of the guests at the supper suggested by telephone that he suspected the onions used in the turkey dressing to be the cause of the trouble. Investigation showed that a bulb, later positively identified as a daffodil bulb, was unknowingly substituted for onions used in making the turkey dressing. As turkey dressing was eaten by all the guests and as daffodil bulbs are known to be poisonous, producing symptoms of vomiting and diarrhea when eaten, it seems probable that ingestion of portions of a daffodil bulb was responsible for this interesting outbreak.

(Reported by Dr. A. A. Larson, D.P.H., Director of Epidemiology, Department of Health Services and Hospital Insurance, Victoria, B.C., and E. W. R. Best, M.D., D.P.H., Chief, Epidemiology Division, Department of National Health and Welfare, Ottawa, Dominion of Canada.)
